A PROJECT REPORT
ON

Brewin Cafe Website

By

Manas Chagan Lad

Towards The Partial Fulfillment of the
Bachelor of Computer Application

Global Education Trust
Mumbai

TYBCA
2025-2026

Tilak Maharashtra Vidyapeeth, Pune

Department of Computer Science

CERTIFICATE

This is to certify that the project
"Brewin Cafe Website"
Has been satisfactorily completed by

Manas Chagan Lad

PRN: 04423003223

Towards The Partial Fulfillment of the 'Bachelor of Computer Application',
For the Academic Year 2025-2026 at Global Education Trust Center,
Mumbai,
Tilak Maharashtra Vidyapeeth, Pune (Department of Computer Science), And
it is approved.

Project Guide **Examiner** **Head of Department**
[GET– Mumbai]

Tilak Maharashtra Vidyapeeth, Pune

Department of Computer Science

ACKNOWLEDGEMENT

With immense please we are presenting **'Brewin Cafe Website'** Project report as part of the curriculum of '**Bachelor of Computer Application**'. We wish to thank all the people who gave us unending support.

I express my profound thanks to our head of department Mr. Vinit Kakar, project guide and project in charge Mr. Haider Zaidi and all those who have indirectly guided and helped us in preparation of this project.

Manas Chagan Lad

Department of Computer Science

PROJECT SYNOPSIS

The hospitality industry is undergoing a digital transformation, shifting away from manual interactions toward seamless, automated experiences. **Brewin Café** is a full-stack web application designed to bridge the gap between traditional café operations and modern digital convenience.

This project addresses the core challenges of manual ordering—such as preparation delays, communication errors, and payment friction—by implementing a robust **MERN-based** (specifically Node.js, Express, and MongoDB) architecture. The application features a premium, interactive user interface built with **GSAP 3** for high-fidelity animations and **Lenis** for smooth kinetic scrolling, providing an aesthetic that rivals high-end e-commerce platforms.

Key technical highlights include: -

Real-time Order Management: Using **Socket.io** to bridge the gap between the customer and the owner dashboard (KDS), providing instant sound notifications and live status updates.

Secure Online Payments: Full integration with the **Razorpay API** with server-side signature verification via HMAC-SHA256 for maximum security.

Live Tracking System: A dedicated interface for customers to monitor their order's journey from "Requested" to "Delivered" in real-time.

Dynamic Inventory Control: An administrative dashboard that allows the owner to toggle "Sold Out" status for items instantly, reflecting across all client devices without a page reload. In essence, **Brewin Café** represents a significant step forward in hospitality management, offering unprecedented transparency, operational control, and user engagement through the power of advanced web technologies.

Tilak Maharashtra Vidyapeeth, Pune

Department of Computer Science

DECLARATION

I hereby declare that the project entitled, “Brewin Café Website” done at GET, has not been in any case duplicated to submit to any other university for the award of any degree. To the best of my knowledge other than me, no one has submitted to any other university. The project is done in partial fulfillment of the requirements for the award of degree of BACHELOR OF COMPUTER APPLICATION to be submitted as final year 6th semester project as part of our curriculum.

Manas Chagan Lad

Chapter 1:

INTRODUCTION

1.1 Background of the Study

The hospitality sector, specifically quick-service restaurants and cafes, has long relied on manual coordination. However, with the rise of the digital economy, customers now expect the same level of convenience in physical spaces as they do in e-commerce. Brewin Café was conceived as a response to this shift, aiming to create a bridge between physical artisanal coffee making and high-speed digital infrastructure.

- **Comprehensive Problem Statement:**
  Manual café operations suffer from four critical failure points:

1. **Synchronization Latency**: The physical distance between the customer and the kitchen causes unavoidable delays in order transmission.

2. **Data Fragmentation**: Paper-based records make it impossible to perform real-time data analysis on sales trends or inventory velocity.

3. **Communication Overhead**: Staff must manually verify payments and communicate order changes, leading to high labor costs and increased human error.

4. **Customer Transparency**: Customers lack insight into the actual state of their order preparation, leading to perceived waiting times and decreased satisfaction.

1.2 Need for the Project

The hospitality and food-and-beverage (F&B) sector is currently navigating a period of rapid technological integration. In a traditional café business model, several systemic bottlenecks hinder growth and customer satisfaction. The need for **Brewin Café** arises from the following critical areas:

- **Elimination of Operational Human Error**: Manual transcription of orders from the table to the kitchen is a significant source of error. Misread handwriting or forgotten verbal instructions lead to incorrect orders, ingredient wastage, and customer dissatisfaction. A digital system ensures that the kitchen receives exactly what the customer selected.

- **Wait-Time Reduction & Queue Optimization**: Traditional ordering requires customers to stand in physical queues or wait for staff to attend to them. During peak hours, this leads to floor congestion and potential revenue loss as customers walk away. Brewin Café allows for simultaneous ordering from multiple devices, significantly reducing the "order-to-delivery" time.

- **Real-time Inventory & Menu Synchronicity**: One of the most common friction points in a café is a customer ordering an item only to be informed minutes later that it is out of stock. Brewin Café's administrative "Toggle Sold Out" feature ensures the digital menu is a "single source of truth," updating all client interfaces instantly.

- **Financial Transparency & Revenue Security**: Manual payment verification (checking UPI screenshots or counting cash) is prone to errors, fraud, and slow transaction processing. By integrating **Razorpay** with server-side HMAC verification, every transaction is audited and verified before an order is even sent to the kitchen, preventing revenue leakage.

- **Contactless and Hygienic Service**: In a post-pandemic world, customers prioritize hygiene. Digitizing the menu and payment process minimizes physical contact with shared paper menus and cash, aligning the café with modern safety standards.

- **Actionable Data & Business Intelligence**: Manual systems provide very little insight into which items are popular or when the peak traffic hours occur. A digital database allows the owner to track sales patterns, helping in better stock planning and staff scheduling.

- **Brand Perception & High-Fidelity UX**: In the modern market, a café's digital presence is as important as its physical ambiance. The use of premium animations (GSAP) and a smooth UI (Lenis) provides a "vibe" of sophistication and luxury, helping **Brewin Café** stand out in a competitive marketplace.

1.3 Project Overview :

Brewin Café is conceived as a "Smart Café Ecosystem" that transcends the limitations of traditional restaurant websites. It is a high-performance, full-stack application designed to serve as the digital backbone of a modern hospitality business. Unlike basic static menus, Brewin Café provides a live, interactive environment where data flows seamlessly between customers and the establishment in real-time.

The project is built on a robust architecture that prioritizes two distinct but interconnected user experiences:

1. **The Customer (The Guest Interface)**: A premium, boutique-style digital storefront. It leverages high-fidelity animations (GSAP) and smooth kinetic scrolling (Lenis) to provide an aesthetic that mirrors the tactile luxury of a specialty coffee shop. It features a real-time responsive menu, dynamic cart management, and a secure payment gateway.

2. **The Owner (The Command Center)**: A dedicated Kitchen Display System (KDS) designed for rapid fulfillment. It utilizes WebSocket technology (Socket.io) to receive orders instantly with persistent sound notifications, effectively acting as a "live pulse" of the café's operations.

By merging sophisticated frontend design with a reliable Node.js/MongoDB backend, **Brewin Café** ensures that every order is a frictionless journey from the first click to the final sip.

1.4 Objectives of the Project:

The development of **Brewin Café** is guided by several mission-critical objectives aimed at modernizing the F&B industry standards:

- **Seamless Real-Time Synchronization**: To establish a persistent, low-latency bridge between the customer's payment confirmation and the kitchen's display system using Socket.io, ensuring zero delay in order notification.

- **Robust Financial Integrity**: To implement a secure, end-to-end checkout flow via the Razorpay API, utilizing server-side HMAC signature verification to ensure every transaction is 100% verified before processing.

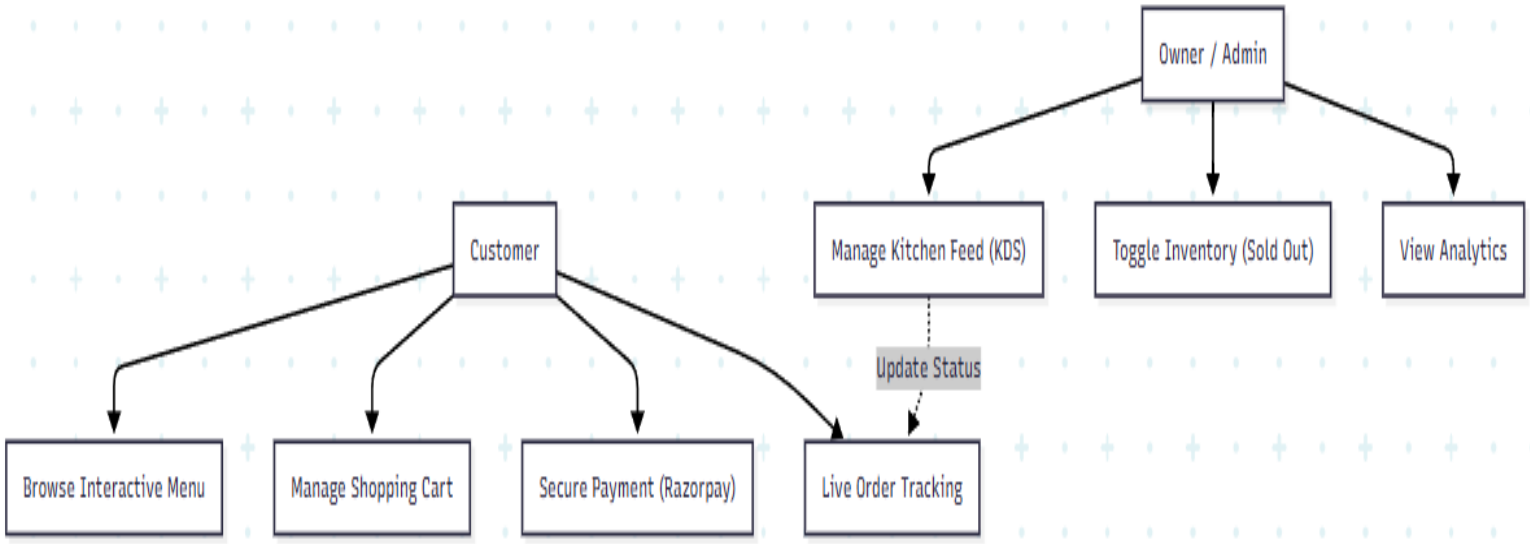
- **High-Fidelity User Engagement**: To craft a "luxury digital atmosphere" using the GSAP 3 animation engine. The objective is to move beyond "utility" and create an "experience" that increases customer time-on-site and brand loyalty.

- **Dynamic Inventory State Management**: To empower the owner with "single-click" control over item availability. The objective is to synchronize "Sold Out" states across all connected client devices instantly without requiring page reloads.

- **Operational Data Centralization**: To consolidate all business data—including order logs, payment references, and customer roles—into a structured MongoDB database for future analytics and auditing.

- **Cross-Platform Accessibility**: To ensure a "Mobile-First" experience, optimizing the UI for various screen ratios so that customers can order effortlessly from any smartphone or tablet.

1.5 Use Case Diagram (System Interactions)



Chapter 2: SYSTEM ANALYSIS

2.1 Problem Definition

2.1.1 Overview of the Problem Domain

The primary challenge addressed by **Brewin Café** is the systemic and deeply rooted inefficiency of manual, analog restaurant operations. The food and beverage (F&B) sector, despite being one of the world's largest and most resilient industries, continues to rely on processes that have not fundamentally changed in decades. Order slips, handwritten receipts, verbal kitchen communication, and physical cash counters remain prevalent in thousands of small-to-medium establishments. These processes, while seemingly simple, introduce compounding layers of error, delay, and financial vulnerability as a business scales.

In high-traffic environments such as a busy urban café, the absence of a digital backbone creates a cascade of operational failures that affect every stakeholder — the customer, the kitchen staff, and the business owner. The following sub-sections deconstruct each problem dimension in critical detail.

2.1.2 Problem 1: Order Miscommunication & Synchronization Failures

In a traditional café, the ordering pipeline involves multiple human handoffs:

1. A customer verbally communicates their order to a waiter.
2. The waiter manually transcribes this order onto a paper slip.
3. The slip is physically carried to the kitchen or announced verbally.
4. Kitchen staff decipher the slip and begin preparation.

Each of these handoffs is a single point of failure. Illegible handwriting, loud ambient noise, language barriers, or simple human memory lapses can cause

orders to be wrong, duplicated, or completely lost. According to a study by the National Restaurant

Association, **order inaccuracies account for up to 10% of customer complaints**, directly impacting repeat business and reputation.

Furthermore, this linear, sequential process cannot handle concurrent volume effectively. During a morning rush hour with 20+ simultaneous customers, a two-person waiter team becomes a critical bottleneck. The time between a customer "deciding" and the kitchen "knowing" can stretch to 10–15 minutes, which is operationally unacceptable in a modern service environment.

Brewin Café solves this by eliminating every human handoff in the ordering chain. The customer directly inputs their order into the digital system. Upon payment confirmation, the order is instantly transmitted via **Socket.io** to the Owner's Kitchen Display System (KDS), reducing the order-to-kitchen time to **under 1 second**, regardless of concurrent order volume.

2.1.2 Problem 1: Order Miscommunication & Synchronization Failures

In a traditional café, the ordering pipeline involves multiple human handoffs

1. A customer verbally communicates their order to a waiter.
2. The waiter manually transcribes this order onto a paper slip.
3. The slip is physically carried to the kitchen or announced verbally.
4. Kitchen staff decipher the slip and begin preparation.

Each of these handoffs is a single point of failure. Illegible handwriting, loud ambient noise, language barriers, or simple

human memory lapses can cause orders to be wrong, duplicated, or completely lost. According to a study by the National Restaurant

Association, **order inaccuracies account for up to 10% of customer complaints**, directly impacting repeat business and reputation.

Furthermore, this linear, sequential process cannot handle concurrent volume effectively. During a morning rush hour with 20+ simultaneous customers, a two-person waiter team becomes a critical bottleneck. The time between a customer "deciding" and the kitchen "knowing" can stretch to 10–15 minutes, which is operationally unacceptable in a modern service environment.

Brewin Café solves this by eliminating every human handoff in the ordering chain. The customer directly inputs their order into the digital system. Upon payment confirmation, the order is instantly transmitted via **Socket.io** to the Owner's Kitchen Display System (KDS), reducing the order-to-kitchen time to **under 1 second**, regardless of concurrent order volume.

2.1.3 Problem 2: Static, Out-of-Date Menu Management

One of the most common and frustrating experiences for a café customer is selecting an item from the menu, waiting for the preparation, and then being told — five minutes later — that the item is unavailable. This friction point arises from an inherent limitation of physical menus: **they cannot reflect real-time inventory states**.

When a popular item like an "Iced Hazelnut Latte" runs out of hazelnut syrup, the only corrective action available to the staff is:

- Writing a correction on a chalkboard (which not every customer may notice).
- Verbally informing each table — a time-consuming and inconsistent process.
- Physically reprinting the menu — which has a direct financial cost and creates delays.

This leads to repeated instances of customer disappointment, negative reviews, and trust erosion. The problem is amplified in cafés that have large menus with dozens of items, as tracking availability across all categories manually is virtually impossible during a busy shift.

Brewin Café resolves this with its **Dynamic "Sold Out" Toggle** feature. From the owner's admin dashboard, a single click on any item immediately flips its `issoldout` flag in the MongoDB database to `true`. The server then broadcasts this state change to all connected client browsers in real-time via Socket.io. The affected item's "Add to Cart" button is **automatically and immediately disabled** across every device accessing the menu, preventing any new orders for that item. This transforms the menu from a static document into a **live, accurate reflection of the kitchen's current capabilities**.

2.1.4 Problem 3: Financial Leakage & Payment Insecurity

In establishments relying on cash or informal UPI transactions, revenue verification is both tedious and unreliable:

- **Cash Handling**: Is subject to counting errors, theft, and provides no verifiable digital audit trail.
- **Manual UPI Verification**: Staff must manually check payment screenshots on a mobile phone for each transaction, a process that is trivially easy to fake and time-consuming at scale.
- **No Automated Order-Payment Linking**: Even if a payment is received, manually linking it to a specific order is an error-prone step. Mix-ups can lead to orders being prepared without corresponding payment, resulting in direct revenue loss.

Furthermore, without a centralized record, the owner has no reliable way to calculate daily revenue, identify which items are most profitable, or detect discrepancies at the end of a shift.

Brewin Café eliminates this vulnerability through its full **Razorpay Integration** with server-side **HMAC-SHA256 Signature Verification**. An order is only marked as "Paid" and forwarded to the KDS **after the server cryptographically verifies that the payment signature matches**. This creates an unbroken, automated chain: Payment Attempt → Bank Confirmation → Signature Verification → Order Activation. No human verification step is required, and every transaction is stored in the MongoDB database with a unique `razorpayPaymentId` for complete audit capability.

2.1.5 Problem 4: Zero Real-Time Visibility for Customers

A pervasive frustration in the traditional café model is the complete lack of transparency once an order is placed. After ordering, a customer enters a "black box" — they have no way to know:

- If their order was received correctly by the kitchen.
- What position their order holds in the queue.
- Whether their item is being prepared, is ready for collection, or has been delayed.

This ambiguity forces customers to either repeatedly approach the counter to enquire (increasing staff distraction) or to simply wait anxiously, which degrades the overall experience and perceived quality of the café.

Brewin Café addresses this with its **Live Order Tracking System**. After payment, the customer is redirected to a dedicated tracking page that displays real-time status updates via a visual, animated timeline. As the owner updates the order status in the KDS (e.g., from *Preparing* to *Ready*), a Socket.io event pushes this update to the customer's tracking page **instantly**, without any page refresh required. This creates the same level of satisfaction and transparency found in premium food delivery apps like Swiggy or Zomato.

2.2 Existing System vs. Proposed System

2.2.1 Analysis of the Existing (Manual) System:

The existing system at a typical small-to-medium Indian café operates on a completely manual, human-dependent workflow. Understanding this system's architecture is essential to appreciating the depth of improvement that **Brewin Café** delivers.

Existing System Workflow:

1. **Discovery**: The customer reads a physical paper/laminated menu or a chalkboard. They have no way to filter by category, check live availability, or see descriptions or images of items.

2. **Ordering**: A waiter takes a verbal or handwritten note of the order. This is manually transcribed onto a KOT (Kitchen Order Ticket) — a paper slip.

3. **Kitchen Communication**: The KOT is physically brought to the barista or kitchen team. If multiple orders arrive simultaneously, prioritization is subjective and often incorrect.

4. **Payment**: The customer either pays cash (requiring a human to calculate change) or makes a UPI transfer (requiring a human to visually verify the screenshot and amount on a phone).

5. **Record-Keeping**: Daily revenue is tallied manually at the end of the shift from collected cash and a review of phone messages. There is no structured database.

Identified Weaknesses of the Existing System:

- **Speed**: The entire process is bottlenecked by the number of available staff members.
- **Accuracy**: Multiple manual transcription steps introduce error at each stage.
- **Scalability**: The system degrades proportionally as order volume increases.
- **Transparency**: Neither the customer nor the owner has a holistic, real-time view of the operation.
- **Security**: Payment verification relies on human judgment and can be circumvented.
- **Business Intelligence**: No structured data means no analysis, no reporting, and no strategic planning.

2.2.2 The Proposed System: Brewin Café

The proposed system replaces every identified weakness of the manual model with a technology-driven, automated equivalent.

Proposed System Workflow:

1. **Discovery**: The customer accesses a dynamic, categorized digital menu on any device. Items marked as "Sold Out" are visually indicated and unorderable. High-quality item descriptions are available.
2. **Ordering**: The customer adds items to a persistent digital cart. Cart state is maintained in `local Storage`, ensuring it survives a page refresh.
3. **Payment**: The customer proceeds to checkout. Razor pay opens a secure modal with multiple payment options (UPI, Cards, NetBanking, Wallets). The server verifies the transaction signature automatically.

4. **Kitchen Notification**: Upon verified payment, a Socket.io event fires, instantly delivering the complete order details to the Owner's KDS with an audio alert. The order appears as a card on the KDS with a real-time countdown.

5. **Tracking**: The customer is redirected to their personal tracking page, where they watch the order progress through animated stages in real-time.

6. **Record-Keeping**: All order data, including payment references, items ordered, status history, and timestamps, is stored in a structured MongoDB document for future retrieval and analysis.

2.2.3 Detailed Feature-by-Feature Comparison

Features	Existing System (Manual)	Proposed System (Brewin Café)	Improvement Factor
Order Input	Verbal/Handwritten slips by waiter	Digital, self-service touch-friendly UI	Eliminates transcription errors
Menu Updates	Physical re-printing / Chalkboard erasing	Single-click "Sold Out" toggle, instant broadcast	Real-time, zero material cost
Payment Processing	Cash counting / Manual UPI screenshot check	Automated Razorpay + HMAC-SHA256 verification	100% secure, no human step required

Kitchen Notification	Physical KOT slip / Verbal announcement	Socket.io event with audio alert (sub-1 second)	Near-instantaneous, no staff required
Order Status Tracking	Customer must physically ask staff	Live animated progress bar on dedicated page	Customer self-service, reduces interruptions
Concurrent Order Handling	Degrades with staff count	Server-side event queue, handles N+ simultaneous	Infinite scalability
Revenue Recording	Manual tally at end of shift	Automatic MongoDB entry on every confirmed payment	100% accurate, real-time record
Inventory Control	Reactive (staff manually marks items unavailable after they run out)	Proactive (owner toggles before items run out entirely)	Better stock planning
Customer Data	No data collected	User accounts with order history stored in DB	Foundation for loyalty programs
Error Resolution	Manual dispute between customer and staff	Full audit trail: `razorpayPaymentId`, order documents in DB	Objective, data-driven resolution

2.3 Feasibility Study

A comprehensive feasibility study was conducted before committing to the development of **Brewin Café**. The study evaluates the project across five critical dimensions to ensure its viability and long-term sustainability.

2.3.1 Technical Feasibility

Technical feasibility : assesses whether the available technology is mature, capable, and accessible enough to support the project's requirements.

Runtime & Backend: Node.js + Express.js

Node.js, built on Google's V8 JavaScript engine, uses a **non-blocking, event-driven I/O model**. This architecture is uniquely suited for the café management use case. Unlike traditional thread-per-request server models (like Java Servlet Containers), Node.js can handle thousands of concurrent WebSocket connections without spawning new threads — a critical requirement for a real-time system where multiple customers and the owner are all connected simultaneously. The **Express.js** framework provides a lightweight and battle-tested routing solution that requires minimal boilerplate to implement the required REST API endpoints.

Database: MongoDB Atlas

MongoDB's **document-oriented** data model is a natural fit for order management. An order in a café is inherently a nested structure (an order contains an array of items, each with a quantity and price). Representing this in a relational (SQL) database would require multiple JOIN operations across tables. In MongoDB, a single Order document can embed the entire item list, making reads significantly faster and the schema more intuitive.

MongoDB Atlas (the cloud-hosted service) additionally provides **automated backups, replica sets, and horizontal scaling** without any infrastructure management overhead from the developer.

Real-Time Communication: Socket.io v4

Socket.io is the industry-standard library for bi-directional, event-driven WebSocket communication. It includes automatic fallback mechanisms (long-polling) for environments where WebSocket connections are blocked by firewalls. For Brewin Café, Socket.io manages the persistent connection between the server, the customer's tracking page, and the owner's KDS. The library's **room** functionality allows targeted event broadcasting — for example, sending a status update only to the specific customer who placed an order, rather than broadcasting to all connected users.

Payment Gateway: Razorpay

Razorpay is a PCI-DSS compliant payment gateway with robust support for the Indian payments ecosystem (UPI, RuPay, IMPS, and all major card networks). The availability of a well-documented JavaScript SDK (`razorpay.js`) for the frontend and a Node.js-compatible server library makes integration straightforward. The HMAC-SHA256 signature verification mechanism provides a cryptographic guarantee that no payment amount can be tampered with between the client and the server — a non-negotiable requirement for financial integrity.

Conclusion : The technology stack is **technically feasible. All chosen technologies are open-source (or have generous free tiers), well-documented, actively maintained, and proven at production scale by thousands of global companies.**

2.3.2 Economic Feasibility

Economic feasibility : assesses whether the project delivers sufficient value relative to its development and operational costs.

Development Costs:

Technology Stack : The core stack (Node.js, MongoDB Atlas Free Tier, Socket.io) incurs **zero licensing cost**. These are open-source or freemium cloud services.

Razorpay Transaction Fee: Razorpay charges a standard fee of ****2% per successful transaction****. This is a percentage of revenue, not a fixed cost, making it a low-risk model for a small business.

Hosting: Services like ****Render, Railway, or Vercel**** offer free hosting tiers sufficient for a prototype or small-scale production deployment.

Projected Cost Savings for the Café Owner :

| Cost Area | Traditional System (Monthly) | With Brewin Café (Monthly) | Savings |

| :--- | :--- | :--- | :--- |

| Printed Menu Reprinting | ₹500 – ₹2,000 | ₹0 (digital menu) | ₹500 – ₹2,000 |

| KOT Paper & Printing | ₹300 – ₹800 | ₹0 (digital KDS) | ₹300 – ₹800 |

| Order Error Waste (Remakes) | ₹1,000 – ₹3,000 | ₹0 – ₹200 (rare edge cases) | ₹800 – ₹2,800 |

| Staff Overtime (Order management) | Variable | Reduced by more efficient workflow | Significant |

Revenue Opportunities Created:

- By eliminating queue frustration, the system can convert walk-aways into seated customers, directly increasing covers served per hour.

- Digital order history enables data-driven promotions and loyalty programs, increasing customer lifetime value.

- The premium UX (GSAP animations, smooth scroll) differentiates the brand, enabling the café to position itself as a premium outlet and charge a higher price point.

Conclusion: The project has a ****high Return on Investment (ROI)****. The operational savings begin from day one, while the development cost for this academic prototype is essentially zero. For a commercial deployment, the system can pay for itself within the first month of operation.

2.3.3 Operational Feasibility

Operational feasibility determines whether the system can be effectively adopted and used by the intended users in their real working environment.

For the Customer (Ease of Use) :

The customer-facing application is designed around the principles of ****intuitive UX****. There is no need to create an account to place an order — a guest checkout flow is supported. The interface is ****mobile-first****, designed for single-handed use on a smartphone, which covers the majority of real-world usage scenarios. The visual hierarchy — from menu to cart to payment — mirrors the cognitive flow of a user's decision-making process, requiring no training or prior knowledge.

For the Owner/Staff (Ease of Administration) :

The Owner's KDS dashboard is deliberately simplified. The owner needs to perform only two types of actions:

1. **Click a button to update order status :** (e.g., move an order from "Preparing" to "Ready").

2. **Toggle the "Sold Out" flag :** for a menu item.

No technical knowledge is required. The interface uses large, clearly labeled controls, high-contrast visuals, and audio feedback to minimize the chance of user error in a fast-paced kitchen environment. The audio notification system means the owner does not need to havethe dashboard constantly in their line of sight — the sound will alert them to new orders even when they are occupied.

System Adoption Strategy:

The dual-purpose nature of the system — serving both customers and the owner on the same technical infrastructure — means it can be introduced gradually. The owner can begin using only the KDS initially, while the customer-facing ordering portal is introduced as a supplementary channel alongside the existing manual process. This phased adoption approach eliminates all-or-nothing risk.

Conclusion: The system is ****highly operationally feasible****. Its design philosophy prioritizes simplicity for both user types. It can be adopted without any disruption to existing operations and does not require the owner or customers to have any prior technological expertise.

2.3.4 Legal & Compliance Feasibility

Any system handling financial transactions and customer data must adhere to applicable legal and regulatory standards.

Payment Compliance: By delegating the actual payment capture to ****Razorpay****, the system leverages Razorpay's existing ****PCI-DSS (Payment Card Industry Data Security Standard)**** compliance. Brewin Café's server never directly handles raw card numbers or CVVs, meaning the compliance burden on the application is significantly reduced.

Data Privacy: Customer passwords are never stored in plaintext. The system uses **bcrypt** to hash passwords before persisting them in MongoDB, ensuring that even if the database is compromised, customer credentials are not exposed. This aligns with data protection best practices as outlined by India's ****IT Act, 2000 (Amended 2008)****.

GSTIN & Financial Records: The structured order database with `razorpayPaymentId` references serves as a verifiable financial ledger, which can be used for GST reconciliation if the café is a registered business entity.

Conclusion: The system is ****legally and compliance-feasible**** for its intended deployment context within India.

CHAPTER 3: SYSTEM DESIGN

System design is the phase where the conceptual requirements identified during system analysis are translated into a concrete blueprint for building the application. This chapter documents the complete technical architecture of **Brewin Café**, including all software and hardware dependencies, the overall system structure, and a deep-dive into every technology chosen for the stack. Each decision is accompanied by a professional rationale explaining why that particular tool was selected over its alternatives.

3.1 Software & Hardware Requirements

System design begins with a thorough inventory of every tool, platform, library, and piece of infrastructure required to build and operate the application. This section documents all software and hardware dependencies of **Brewin Café**, along with a clear justification for each selection

3.1.1 Software Requirements

A. Programming Languages

The Brewin Café application is built entirely using web-standard programming languages, ensuring maximum compatibility and zero licensing cost. The three core languages — JavaScript, HTML5, and CSS3 — together form the complete presentation and logic layer of the application.

Language	Version	Role in the Project
JavaScript (ES6+)	ECMAScript 2017+	Primary language for both frontend interactivity and the backend server logic
HTML5	Living Standard (W3C)	Provides the semantic structural foundation for all web pages
CSS3	Modern Standard (W3C)	Handles all visual styling, layout systems (Flexbox, CSS Grid), and responsive design

The decision to use **JavaScript across the entire stack — a pattern known as "Isomorphic JavaScript" — provides a significant productivity advantage. With a single language shared between the frontend and backend, the developer eliminates the cognitive overhead of switching between two different languages and ecosystems. This unified language environment allows data models, validation rules, and utility functions to be written once and shared across both the client and server sides of the application.**

B. Runtime Environment & Web Framework

The server-side runtime and framework form the backbone of the application, responsible for handling all incoming requests, executing business logic, and sending appropriate responses.

Component	Tool & Version	purpose
Server Runtime	Node.js v18.x (LTS)	Executes JavaScript on the server outside of a browser environment
Package Manager	npm : (Node Package Manager)	Manages and installs all third-party library dependencies
Web Framework	Express.js v4.x	Provides routing, middleware pipeline, and HTTP utility methods

Node.js v18 (LTS was specifically chosen over other versions because it carries a Long-Term Support guarantee, meaning it receives security patches and stability updates for a minimum of 30 months. This makes it the appropriate choice for any production-grade or academically submitted system. Node.js operates on a non-blocking, event-driven I/O model — meaning the server can handle many simultaneous connections without creating a new processing thread for each one, making it highly efficient for real-time café applications.

Express.js was selected for its deliberate minimalism. Unlike heavier frameworks that impose rigid project structures and generate large amounts of automatic code, Express gives the developer complete control over how routes, middleware, and error handling are organized. This transparency is essential for a project where every architectural decision needs to be understood and explained.

C Database :

The data layer of Brewin Café is responsible for persistently storing all users, products, and orders in a structured and retrievable format.

Component	Tool & Version	purpose
Database Engine	MongoDB v6.x	Document-oriented NoSQL database for flexible data storage
Cloud Hosting Service	MongoDB Atlas (Free M0 Tier)	Zero-infrastructure, cloud-hosted database with automated backups
Object Data Modeling (ODM)	Mongoose v7.x	Provides schema definition, field validation, and an expressive query API on top of MongoDB

MongoDB : was selected over traditional relational databases (such as MySQL or PostgreSQL) because the primary data structure in this application — the Order — is inherently hierarchical. A single order contains an embedded list of multiple items, each with its own quantity and price. In a relational database, this would require a minimum of two separate tables joined by a foreign key, increasing query complexity. In MongoDB, the entire order, including all its items, is stored as a single, self-contained document, making retrieval significantly faster and the data model far more intuitive to work with.

MongoDB Atlas : provides the cloud infrastructure, eliminating the need to manually install, configure, or maintain a local database server. The free M0 tier provides 512 MB of cloud storage, automated daily backups, and a globally distributed replica set — all without any cost to the developer.

D. Frontend Libraries & Animation

The visual layer of Brewin Café goes beyond standard HTML and CSS to incorporate specialized animation and scrolling libraries that deliver a premium, boutique-level user experience.

Library	Version	purpose
GSAP (GreenSock Animation Platform)	v3.12+	Powers all high-performance UI animations including page loads, reveals, and transitions
Lenis	v1.x	Replaces the browser's native scroll with a smooth, physics-based inertial scrolling experience
Vanilla CSS	_	Handles all layout, theming, color palettes, and responsive media queries

The decision to use **Vanilla CSS** instead of a framework like Bootstrap or Tailwind CSS was deliberate. CSS frameworks impose a pre-built design vocabulary that leads to visually generic interfaces. For Brewin Café, the design goal was a custom, brand-specific aesthetic that communicates the sophistication of a premium urban café. Writing CSS from scratch provides complete creative control over every visual detail — which is impossible to achieve cleanly within the constraints of a utility-first CSS framework.

E. Payment & Security Libraries

The security and payment layer is critical to the trustworthiness of the system. The following libraries handle user authentication, data protection, and financial transaction processing.

Library	Purpose
Razorpay Node.js SDK	Used on the server side to create verified payment orders and validate transaction signatures
Razorpay Checkout JS	The client-side SDK that renders the secure payment modal for the customer
bcryptjs	Hashes user passwords using the bcrypt algorithm before storing them in the database
jsonwebtoken (JWT)	Generates and verifies authentication tokens for secure, stateless user sessions
dotenv	Loads sensitive configuration values (API keys, database URIs) from a private environment file
cors	Configures the server's Cross-Origin Resource Sharing policy to control which domains can make API requests

3.1.2 Hardware Requirements

A. Server-Side Requirements

The server-side hosting environment runs the Node.js application and manages all incoming connections from customers and the owner's kitchen display system.

Requirement	Minimum Specification	Recommended Specification
Processor	Single-core 1 GHz	Dual-core 2 GHz or higher
RAM	512 MB	1 GB to 2 GB
Storage	500 MB	1 GB or more
Network Speed	10 Mbps	100 Mbps or higher
Operating System	Ubuntu 20.04 LTS or Windows Server 2019	Ubuntu 22.04 LTS

For this academic project, **Render.com** (free hosting tier) is used as the deployment platform. Render automatically provisions a server environment with adequate resources for a prototype-scale deployment. The **MongoDB Atlas M0 Free Tier** serves as the cloud database host, providing 512 MB of storage and a distributed replica set at zero cost — fully sufficient for this project's data volume.

B. Client-Side Requirements :

The client-side requirements define the minimum device and browser specifications needed for a customer or café owner to use the application effectively.

Requirement	Specification
Device Type	Any smartphone, tablet, laptop, or desktop computer
Browser	Google Chrome 90+, Mozilla Firefox 88+, Microsoft Edge 90+, Safari 15+
Internet Connection	Minimum 2 Mbps (required for stable WebSocket connections)
Minimum Screen Width	360 pixels (designed Mobile-First for smartphone usage)

The ****Mobile-First design philosophy**** was adopted based on the observed reality that the majority of café customers will access the ordering system from their personal smartphones rather than from a desktop computer. The entire user interface was therefore designed and tested first on a 390-pixel viewport (equivalent to an iPhone 14) before being scaled up to accommodate larger screens.

3.2 System Architecture

The overall structure of **Brewin Café** is governed by two complementary architectural principles: the **Client-Server Model** for defining how the system's components interact across a network, and the **MVC (Model-View-Controller)** pattern for organizing the internal code of the server-side application. Together, these patterns ensure the system is logically separated, easy to maintain, and professionally structured.

3.2.1 The Client-Server Architecture

In a Client-Server architecture, the system is cleanly divided into two primary roles that operate across a network: the **Client**, which handles everything the user sees and interacts with, and the **Server**, which handles all processing, data management, and security-critical operations. This separation creates a clean boundary between presentation and logic, ensuring that no sensitive information such as database credentials, payment API keys, or authentication secrets is ever exposed to the end user's browser.

The **Client** is the web browser running on the customer's or owner's device. The browser is responsible exclusively for displaying the user interface and capturing user interactions such as button clicks, form submissions, and scroll events. The browser never directly accesses the database or holds any sensitive business logic.

The **Server** is the Node.js application running on a cloud hosting platform. The server is responsible for all the critical work: validating request data, executing business rules, communicating with the database, interacting with the Razorpay payment gateway, and managing all real-time WebSocket connections.

The **Customer Browser** communicates with the server via two channels simultaneously: standard HTTP requests (for fetching menu data, submitting orders, and logging in) and a persistent WebSocket connection via Socket.io (for receiving live order status updates). The **Owner's KDS Browser** similarly maintains a permanent WebSocket connection to receive instant notifications whenever a new, verified order arrives.

3.2.2 The MVC (Model-View-Controller) Pattern

The MVC pattern is an architectural design principle that organizes the server-side application into three clearly isolated layers, each with a single, focused responsibility. This separation of concerns means that a change in one layer — for example, updating how an Order document is stored in the database — does not require changes to the user interface or the routing logic. Each layer can be developed, tested, and debugged independently. The diagram below illustrates how the three layers relate to each other and to the external actors in the system.

MVC Architecture Topology:

```

A) The Model Layer — The Data Contract

The Model is the layer responsible for defining the exact structure and validation rules for all data stored in the database. In Brewin Café, this is implemented through **Mongoose Schemas**. Each schema serves as a formal contract, specifying precisely which fields a database document must contain, the data type of each field, which fields are mandatory, and what values are considered valid. For example, the Order schema enforces that the payment status field can only ever contain one of three permitted values: "pending", "paid", or "failed". Any attempt to save a document that violates these rules is automatically rejected by Mongoose before it ever reaches the database. The Model layer has no knowledge of HTTP requests or the user interface — it exists solely to define and protect the integrity of data.

Schema	Key Fields	Validation Rules
UserSchema	name, email, password, role	email must be unique; role is an enum of "customer" and "admin"
ProductSchema	name, category, price, isSoldout	category is an enum of fixed values; price must be a positive number
OrderSchema	orderId, customer, items, status, paymentStatus, total	status and paymentStatus are enums; items is a nested array of product references

B) The View Layer — The Presentation

The View is the layer that the user directly interacts with — it is everything rendered in the browser. In Brewin Café, the View layer consists of HTML5 pages whose content is dynamically populated by client-side JavaScript. Rather than using a server-side templating engine, the Brewin Café approach sends a lightweight HTML skeleton to the browser, which then fetches the necessary data from the API and renders the content dynamically. This approach enables a faster, more app-like experience, as subsequent interactions update only specific parts of the page rather than reloading it entirely. The View layer connects to the GSAP animation engine and the Socket.io client, but never reads from or writes to the database directly — all data requests are routed through the server's API.

View Page	Purpose	Key Interactions
loder.html	Brand entry point with loader animation	GSAP timeline, text descrambler effect
index.html	Main landing page and menu	Fetches products from API, manages cart in localStorage
checkout.html	Cart review and payment initiation	Sends order to server, opens Razorpay modal
track.html	Live order tracking page	Socket.io connection for real-time status updates
owner.html	Kitchen Display System (KDS)	Socket.io listener for new orders, status update buttons

The Controller Layer — The Business Logic

The Controller is the intermediary that sits between the Model and the View. In Brewin Café, each controller is an Express.js route handler function — triggered whenever the server receives a specific HTTP request. When a request arrives, the controller follows a strict sequence: it first validates the incoming data; it then calls the appropriate Model functions to read or write data; it executes business logic (such as computing a cryptographic payment signature or decoding an authentication token); and finally returns a structured response back to the browser. Controllers are deliberately thin — they delegate data concerns to the Model and presentation concerns to the View.

Controller	Route Handled	Business Logic Executed
authController	POST /api/auth/register, POST /api/auth/login	bcrypt hashing on register; bcrypt compare + JWT generation on login
productController	GET /api/products, PATCH /api/products/:id	Fetches menu items; toggles isSoldOut flag and broadcasts via Socket.io
orderController	POST /api/orders/create	Creates Razorpay order, stores pending order in MongoDB
paymentController	POST /api/payment/verify	HMAC-SHA256 verification; marks order as paid; emits Socket.io event
trackController	GET /api/orders/track/:orderId	Fetches specific order document by ID for the tracking page

3.2.4 Authentication & Security Architecture

Brewin Café implements a **stateless, token-based authentication system** using JSON Web Tokens (JWT) and the bcrypt hashing algorithm. This approach was chosen because it requires no server-side session storage — the authentication state is entirely contained within a compact, digitally signed token held by the client's browser.

The authentication flow operates as follows: When a new user registers, their password is processed through the bcrypt algorithm with ten computational rounds of salt-based hashing before being stored in the database. This means the actual password is never saved anywhere — only an unreadable hash. When the user attempts to log in, bcrypt compares the entered password against the stored hash without ever reversing the hash itself. If the comparison succeeds, the server generates a JWT containing the user's unique database identifier and their role (either "customer" or "admin"), signs it with a private secret key, and returns it to the browser.

On every subsequent request to a protected API route (such as placing an order or viewing the admin dashboard), the browser sends this token in the request header. An Express.js middleware function intercepts the request, verifies the token's digital signature to confirm it has not been tampered with, and extracts the user's identity from it. If the token is invalid, expired, or absent, the request is immediately rejected with a 401 Unauthorized error. For routes that are exclusively accessible to the café owner, an additional check confirms that the user's role is "admin" before allowing access.

3.3 Technology Stack Deep Dive

This section provides a comprehensive professional analysis of each major technology chosen for the Brewin Café stack. For every tool, the discussion addresses what the technology is, the specific problem it solves within this project, why it was selected over its alternatives, and how its core concepts apply to the application's functionality.

3.3.1 Node.js — The Server-Side Runtime Environment

Node.js is an open-source, cross-platform JavaScript runtime environment that allows JavaScript code — traditionally a language that could only run inside a web browser — to be executed directly on a server. It is built on top of Google Chrome's V8 JavaScript engine, which compiles JavaScript to machine code for maximum execution speed.

The fundamental architectural characteristic that makes Node.js uniquely suitable for **Brewin Café** is its **non-blocking, event-driven I/O model**. In traditional server environments (such as those built with PHP or Java Servlets), each incoming client connection is handled by its own dedicated processing thread. When a thread is waiting for a response from the database or a payment gateway, it sits idle, consuming memory while doing no useful work. As the number of simultaneous users grows, the server must spawn proportionally more threads, consuming significant resources. In contrast, Node.js operates on a single thread and uses an **event loop** to manage all concurrent operations. When the Node.js server sends a database query, it does not wait idle — it registers a callback function to be executed when the result arrives and immediately moves on to handle the next incoming request. This approach allows a single Node.js process to efficiently handle thousands of simultaneous connections, which is precisely what is needed when multiple customers and the café owner are all connected to the system at the same time, some over HTTP and others over persistent WebSocket connections.

3.3.2 Express.js — The Web Application Framework

Express.js is a minimal and unopinionated web application framework for Node.js. While Node.js itself provides the capability to create an HTTP server, doing so from scratch requires handling a large amount of low-level detail. Express.js abstracts this complexity into a clean, readable API for defining routes and writing middleware.

The most significant architectural feature of Express.js used in Brewin Café is its ****middleware pipeline****. Every HTTP request that arrives at the server passes through a configurable chain of functions before reaching its destination route handler. In Brewin Café, this pipeline first applies the CORS middleware (which controls which browsers are permitted to make API calls), then the JSON body parser (which converts the raw request body into a usable JavaScript object), and then the authentication middleware (which verifies the user's identity token). Only after passing through this chain does the request reach the actual business logic of the route handler. This pipeline structure keeps every layer of concern neatly separated and individually testable.

Express routes in Brewin Café are organized into separate ****Router files**** grouped by domain: one file contains all authentication-related routes, another contains all product-related routes, and a third contains all order-related routes. Each router is then mounted on the main application at a specific path prefix, creating a well-organized and maintainable API structure.

3.3.3 MongoDB & Mongoose — The Database Layer

MongoDB is a document-oriented NoSQL database that stores data in the form of flexible, JSON-compatible documents (internally stored in a binary format called BSON) rather than in rigid rows and columns. This fundamental difference in data structure has significant practical implications for the way Brewin Café stores and retrieves its data.

Consider the structure of an order. An order in a café contains multiple items, and each item has a name, a quantity, and a price. In a traditional relational database, this would require at least two separate tables: one for the order's header information (total amount, payment status, delivery status) and a second for the line items, linked to the first table by a foreign key. Every time the application needs to display a complete order, it must execute a JOIN operation to combine data from both tables — an operation that adds complexity and processing time. In MongoDB, the entire order — including all its nested items — is stored as a single, self-contained document. Reading a complete order requires a single database query with no joining, resulting in simpler application code and faster data retrieval.

****Mongoose**** adds a critical layer of structure on top of MongoDB's inherent flexibility. Because MongoDB accepts documents of any shape, it is entirely possible — without a safeguard — to accidentally save an order document with a missing payment status, or a product document without a price. Mongoose Schemas prevent this by defining a strict blueprint for each type of document, specifying exactly which fields are required, their expected data types, and what values are considered valid. Any document that does not conform to the schema is rejected with a validation error before it reaches the database. Mongoose also provides the highly useful ****populate**** feature, which automatically replaces a stored reference to another document (such as a product ID inside an order's item list) with the actual product data — eliminating the need for separate lookup queries.

3.3.4 Socket.io — The Real-Time Communication Engine

Socket.io is a JavaScript library that enables real-time, bi-directional, event-based communication between a server and one or more web browsers simultaneously. It is built on top of the WebSocket internet protocol, which fundamentally differs from the standard HTTP protocol that governs most web communication.

Standard HTTP communication is inherently one-directional and transactional: the client (browser) sends a request, the server sends back a response, and the connection closes. The client must initiate every interaction. This model is completely unsuitable for the real-time features of Brewin Café, because the server needs to be able to ****proactively push data to connected browsers**** — for example, immediately notifying the kitchen display system when a new order arrives, or instantly updating the customer's tracking page when the owner changes the order status.

The WebSocket protocol, which Socket.io uses, establishes a single persistent, open connection between the browser and the server. This connection remains open for the duration of the user's session, allowing either party to send messages to the other at any moment without the overhead of establishing a new connection each time.

The following table illustrates the key differences between the two communication models:

A key Socket.io feature used in Brewin Café is the concept of ****Rooms****. When a customer navigates to their order tracking page, their browser automatically joins a Socket.io "room" identified by their unique order number. When the café owner updates an order's status, the server emits the update event exclusively to the room corresponding to that specific order. This means only the customer who placed that particular order sees their tracking page update — other connected users are completely unaffected. This targeted communication model is far more efficient than broadcasting every event to every connected browser.

3.3.5 GSAP — The Animation Platform

GSAP (GreenSock Animation Platform) is a professional-grade JavaScript animation library used extensively by top digital agencies, technology companies, and award-winning websites worldwide. It provides a powerful, declarative API for animating virtually any visual property of HTML elements — including position, opacity, scale, rotation, color, and custom CSS variables — with fine-grained control over timing, easing curves, and sequencing.

While the modern web browser provides built-in CSS animation capabilities, CSS has fundamental limitations when building the type of complex, orchestrated animation sequences that define the Brewin Café branded experience. CSS animations cannot be dynamically paused, reversed, or interrupted based on user behaviour. They cannot animate non-CSS properties or JavaScript values. Sequencing a series of CSS animations on multiple elements requires fragile, hard-coded delay calculations that become extremely difficult to maintain. GSAP resolves all of these limitations elegantly.

The central concept in GSAP is the ****Timeline****: an ordered, programmable sequence of individual animations that play one after another (or in parallel, or with an offset). In Brewin Café, the application's loader page uses a GSAP Timeline to orchestrate the entrance of the brand logo, navigation elements, and hero content in a precisely choreographed sequence that immediately communicates a sense of quality and intention to the user. GSAP's ****ScrollTrigger**** plugin takes this further by linking the progress of animations directly to the user's scroll position, causing sections of the menu to gracefully reveal themselves as the user scrolls down the page. GSAP also powers the "text descrambler" effect — a signature animation where the word "BREWIN" appears to rapidly cycle through random characters before resolving into its final form, creating a distinctive and memorable brand moment.

All GSAP animations operate by applying GPU-accelerated CSS transform properties wherever possible, completely bypassing the browser's expensive layout and paint cycles. This results in smooth, 60-frames-per-second animations even on mid-range mobile devices.

3.3.6 Lenis — The Smooth Scroll Library

Lenis is a lightweight, open-source library dedicated to a single but impactful purpose: replacing the browser's default, mechanical scroll behaviour with a smooth, physics-based inertial scroll experience. The default scroll behaviour in all web browsers is instantaneous — the page jumps directly to the new scroll position when the user moves the mouse wheel or swipes on a touchscreen. While functional, this feels abrupt and mechanical, creating a stark contrast with the premium, tactile quality that the Brewin Café design aims to convey.

Lenis intercepts the scroll event and uses a mathematical technique called ****linear interpolation**** (commonly abbreviated as "lerp") to calculate a smooth transition between the current scroll position and the target scroll position. Instead of jumping, the page gradually decelerates toward the target, creating the physical sensation of momentum and natural resistance — the same feeling that makes luxury mobile apps and high-end brand websites feel distinctively different from ordinary web experiences.

Lenis is carefully integrated with GSAP's ScrollTrigger plugin so that the scroll-triggered animations defined in GSAP respond to Lenis's smoothed scroll position rather than the raw browser position. Without this synchronization, scroll animations would appear to "lag behind" the smoothed page, creating a visually broken experience.

3.3.7 Razorpay — The Payment Gateway

Razorpay is an Indian financial technology company that provides a complete, developer-friendly payment infrastructure. It supports the full breadth of Indian payment methods — including UPI (Google Pay, PhonePe, Paytm), IMPS, NEFT, all major credit and debit card networks (Visa, Mastercard, RuPay), and digital wallets — making it the most appropriate payment gateway for a café system deployed within India.

The Razorpay integration in Brewin Café follows a carefully designed two-phase flow that separates the concern of ****collecting payment**** (handled by Razorpay's secure infrastructure) from the concern of ****verifying payment**** (handled by Brewin Café's own server). This separation is critical for security.

Phase 1 — Order Initiation: When the customer clicks "Checkout", Brewin Café's server contacts the Razorpay API to create a new payment order, specifying the exact amount to be collected (converted into the smallest currency unit, paise). Razorpay responds with a unique order identifier, which the server passes back to the customer's browser.

Phase 2 — Payment Capture: Using this order identifier, the Razorpay Checkout SDK (loaded in the customer's browser) opens a professionally designed payment modal, presenting the customer with all available payment methods. The customer completes the payment through Razorpay's own secure interface — at no point does any sensitive card or banking data pass through Brewin Café's server.

Phase 3 — Cryptographic Verification: After the payment is completed, Razorpay returns three values to the customer's browser: the payment identifier, the order identifier, and a cryptographic signature. The browser immediately forwards all three values to Brewin Café's server. The server then independently computes its own cryptographic signature using the HMAC-SHA256 algorithm with a secret key known only to Razorpay and the server. If the server's computed signature matches the signature provided by Razorpay, the payment is genuine and unaltered. Only at this point is the order's status updated to "Paid" in the database, and only at this point is the Socket.io event fired to notify the kitchen. This three-phase verification flow makes it cryptographically impossible for a malicious user to fake a successful payment.

3.3.8 bcrypt & JWT — Security Libraries

bcrypt is a password hashing function specifically designed for securely storing user passwords. The defining characteristic of bcrypt is its intentional computational slowness — it performs multiple rounds of a key derivation function, making it extremely time-consuming to attempt to crack a hashed password through brute force, even with powerful hardware. In Brewin Café, every user password is processed through ten rounds of bcrypt hashing before being stored. The resulting string is a one-way hash — once created, it cannot be mathematically reversed to reveal the original password. During login, bcrypt re-applies the same hashing process to the entered password and checks whether the result matches the stored hash, allowing verification without ever storing or transmitting the actual password.

JWT (JSON Web Token) is an open standard for creating compact, digitally signed tokens that can securely transmit information between parties. In Brewin Café, after a user successfully logs in, the server creates a JWT containing the user's unique identifier and their role, signs it with a private secret key, and sends it to the browser. The browser stores this token and attaches it to every subsequent API request. The server verifies the token's digital signature on each request, confirming the user's identity without needing to query the database for session information on every call. If the token's content is altered in any way after it was signed, the signature becomes invalid and the request is immediately rejected.

CHAPTER 4: DATABASE DESIGN

4.1 Database Overview

Brewin Café uses **MongoDB** as its database engine, hosted on **MongoDB Atlas** (the cloud-managed version of MongoDB). MongoDB is a **document-oriented NoSQL database**, which stores data in the form of flexible, JSON-like documents rather than in rigid rows and columns like a traditional relational SQL database. This choice was made specifically because the primary data structures in a café management system — particularly orders — are inherently hierarchical and variable in structure.

The database is managed through **Mongoose**, an Object Data Modeling (ODM) library for Node.js. While MongoDB itself is schema-less, Mongoose adds a structured schema layer on top, allowing the development team to enforce strict field types, required fields, value restrictions, and default values for every document in every collection.

Database Technology Summary

Property	Detail
Database Engine	MongoDB v6.x
Hosting Platform	MongoDB Atlas — Free M0 Tier (Mumbai Region)
Data Format	BSON (Binary JSON) — stores as documents
Schema Management	Mongoose v7.x ODM

Number of Collections	3 (users, products, orders)
Cloud Cluster Type	Replica Set (3 nodes for high availability)
Storage	512 MB (sufficient for prototype and early production)
Backups	Automated daily snapshots via MongoDB Atlas
Access Protocol	MongoDB Wire Protocol over TLS-encrypted connection

4.2 Database Collections & Entity Overview :

The Brewin Café database is organized into three distinct collections (the MongoDB equivalent of database tables). Each collection stores a specific category of business data, sand the collections are linked to one another through reference relationships, similar to foreign keys in SQL.

╠═══════════════════════════════════════════════════════════════════════╣
```

4.3 Entity Relationship Overview :

Even though MongoDB is a NoSQL database and does not enforce relationships at the database engine level, the Brewin Café application enforces **logical relationships** between collections through Mongoose's ObjectId referencing system — the NoSQL equivalent of foreign key relationships. The following table summarizes all inter-collection relationships.

```
╔═══════════════════════════════════════════════════════════════════════╗

    │  imageUrl        │
    └──────────────────┘
```

4.4 Data Validation Architecture

Mongoose serves as the primary data validation layer for Brewin Café. Before any document is written to the MongoDB database, Mongoose validates every field against the schema's rules. If any validation fails, the document is rejected and an error is returned to the controller, which then sends an appropriate error response to the client. This ensures the database never contains corrupt, incomplete, or incorrectly formatted data.

Validation Types Used in Brewin Café:

Validation Type	Fields It Protects	How It Works
Required	name, email, password, category, price, items, status	Rejects any document where these fields are absent or null
Unique	email (User), itemId (Product), orderId (Order)	Prevents two documents in the same collection from sharing the same value
Enum	role (User), category (Product), status and paymentStatus (Order)	Restricts the field to a predefined list of permitted string values
Type Checking	All numeric fields (price, qty, total)	Ensures numeric fields cannot be stored as strings, or vice versa

4.5 Document-Oriented Design Justification

A fundamental design decision in Brewin Café is the choice of a ****document-oriented database (MongoDB)**** over a ****relational database (such as MySQL or PostgreSQL)****. The following table provides a direct, side-by-side comparison to illustrate why MongoDB is the more appropriate choice for this system's data structures.

Comparison Criterion	Relational Database (MySQL)	Document Database (MongoDB)	Advantage For Brewin Café
Order Storage	Split across two tables: "orders" and "order_items", joined with a foreign key	Single document containing an embedded "items" array	One query returns the complete order — no JOIN needed
Schema Flexibility	Changing the schema requires a database migration script	New fields can be added to documents without schema migration	Faster iteration during development
Nested Data	Complex to represent (requires additional tables and JOIN operations)	Natural and native (embedded sub-documents)	Order items are a natural nested structure
Read Performance	Multiple JOIN operations for complex queries	Single document read covers all related data	Future scalability with growing order volume

CHAPTER 5: PROJECT MODULES & IMPLEMENTATION

5.1 Frontend Modules

The frontend of Brewin Café is responsible for the entire customer journey. It leverages modern web technologies to ensure that the user experience is fluid, responsive, and visually engaging.

5.1.1 Landing & Onboarding (Loader)

The **Landing & Onboarding** module serves as the initial hook for the user. Its primary goal is to manage the application's heavy asset loading while introducing the user to the "Brewin" brand identity.

The Loder Experience : Upon visiting the site, the user is greeted by a custom "Loder" (Loader) screen. This is not a static loading bar but a dynamic visual sequence powered by **GSAP (GreenSock Animation Platform)**. It features a text-scramble effect where the letters of "BREWIN" are randomly descrambled into place.

Visual Entrance: Once the application assets (images, fonts, scripts) are fully cached, the loader fades away to reveal the hero section. This transition is orchestrated using staggered entrance animations, ensuring that the heading, navigation, and the "Explore" button appear in a rhythmic sequence.

Authentication Recovery : This module also acts as a silent guard. It checks the browser's `localStorage` for a valid JSON Web Token (JWT). If a returning user is detected and their token is still valid, the system automatically authenticates them and transitions them directly to the main menu, providing a zero-friction return experience.

A) Landing & Onboarding (Loader) :

5.1.2 The Interactive Menu

The **Interactive Menu** is the most data-intensive module of the customer interface. It is implemented as a dynamic catalog that allows users to explore the café's offerings with ease.

Dynamic Filtering:

The menu utilizes a filterable grid layout. Users can interact with category buttons (e.g., Coffee, Food, Drinks, Desserts) to instantly narrow down their choices. This is achieved through DOM manipulation that filters products based on their category attributes without requiring a page refresh.

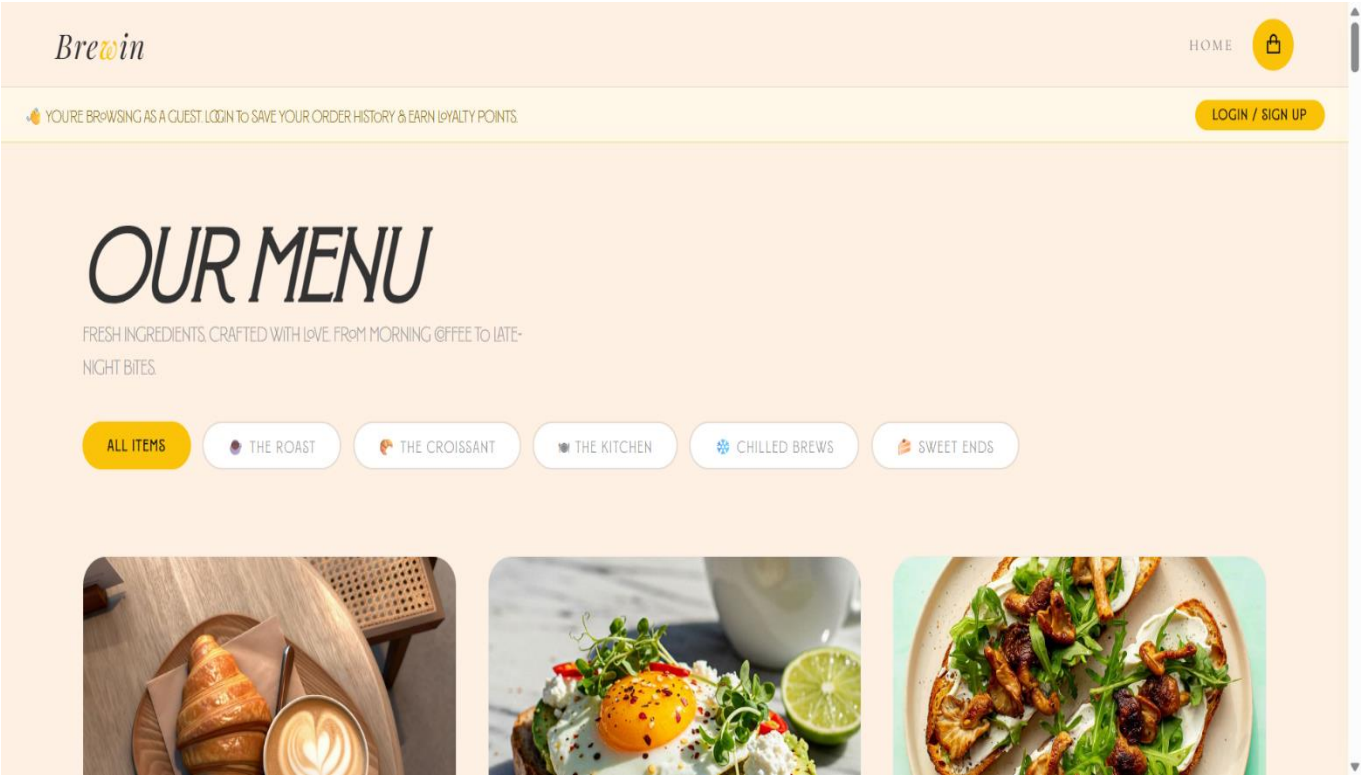
Real-time Inventory Sync:

One of the critical features of this module is its integration with **Socket.io**. If the café owner marks an item as "Sold Out" from the management panel, the menu module receives a real-time event. The UI immediately updates the item card with a "Sold Out" badge, disables the "Add to Cart" button, and greys out the image, preventing any accidental orders of unavailable stock.

Premium Visualization:

Each item card is designed with rich typography and high-resolution imagery. Using the **ScrollTrigger** plugin, items reveal themselves with a subtle zoom and fade effect as the user scrolls, maintaining a high-quality aesthetic throughout the browsing experience.

B) The Interactive Menu :



5.1.3 Shopping Cart & Checkout

The **Shopping Cart & Checkout** module handles the state of selected items and the transition into a secure financial transaction.

Context-Preserving Cart:

The cart is implemented as a sliding-drawer interface. This allows the user to review their selection, modify quantities, or delete items without ever leaving the menu page. The subtotal, taxes, and total amounts are recalculated in real-time using localized state management.

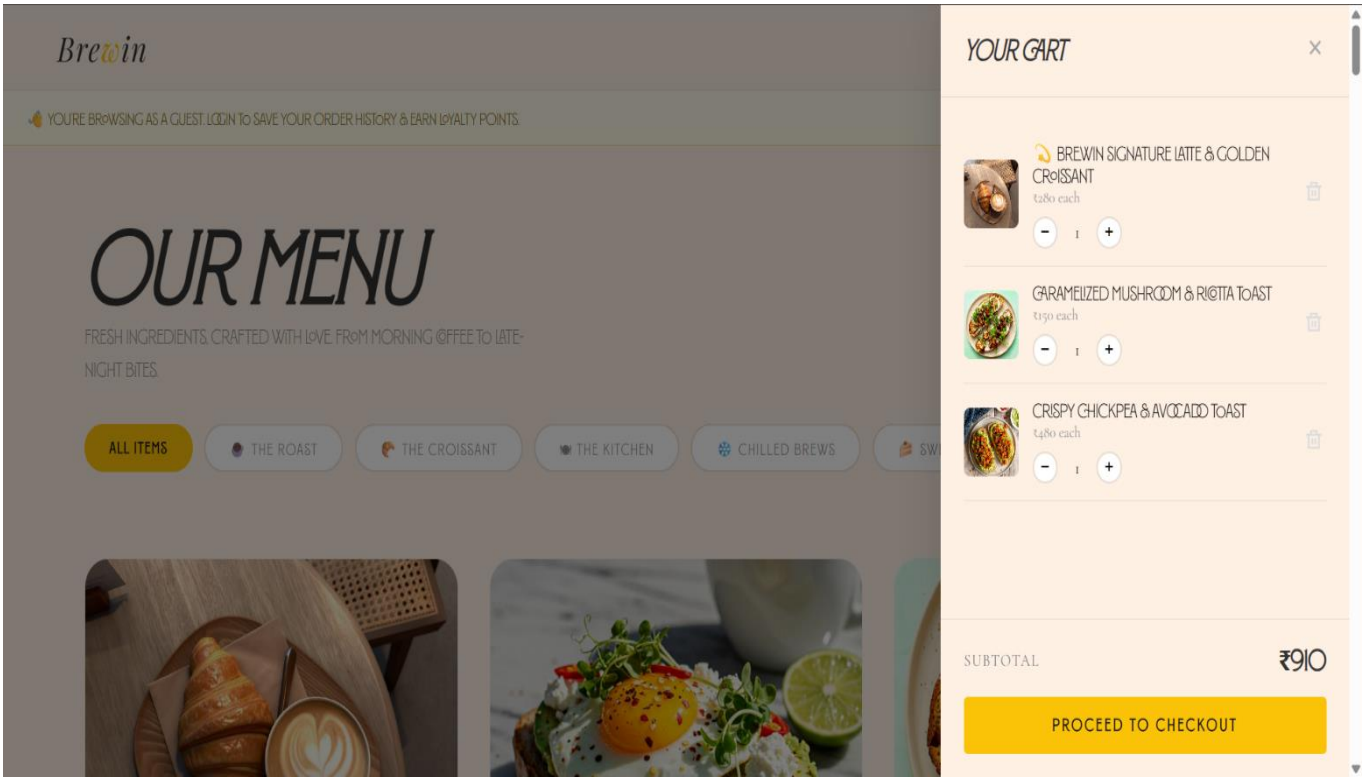
Razorpay Integration Flow:

When the user clicks "Proceed to Checkout", the module initiates a secure handshake with the backend. First, an order is initialized on the server to generate a unique **Razorpay Order ID**. Once received, the official Razorpay payment modal is opened. This modal supports various payment methods including UPI, Credit/Debit Cards, and Netbanking.

Cryptographic Verification:

After the payment is completed on the Razorpay side, the module receives a success response containing a `payment_id` and a `signature`. These are then sent back to the server for final cryptographic verification before the order is officially moved to the "Paid" state in the database.

C) Shopping Cart & Checkout :



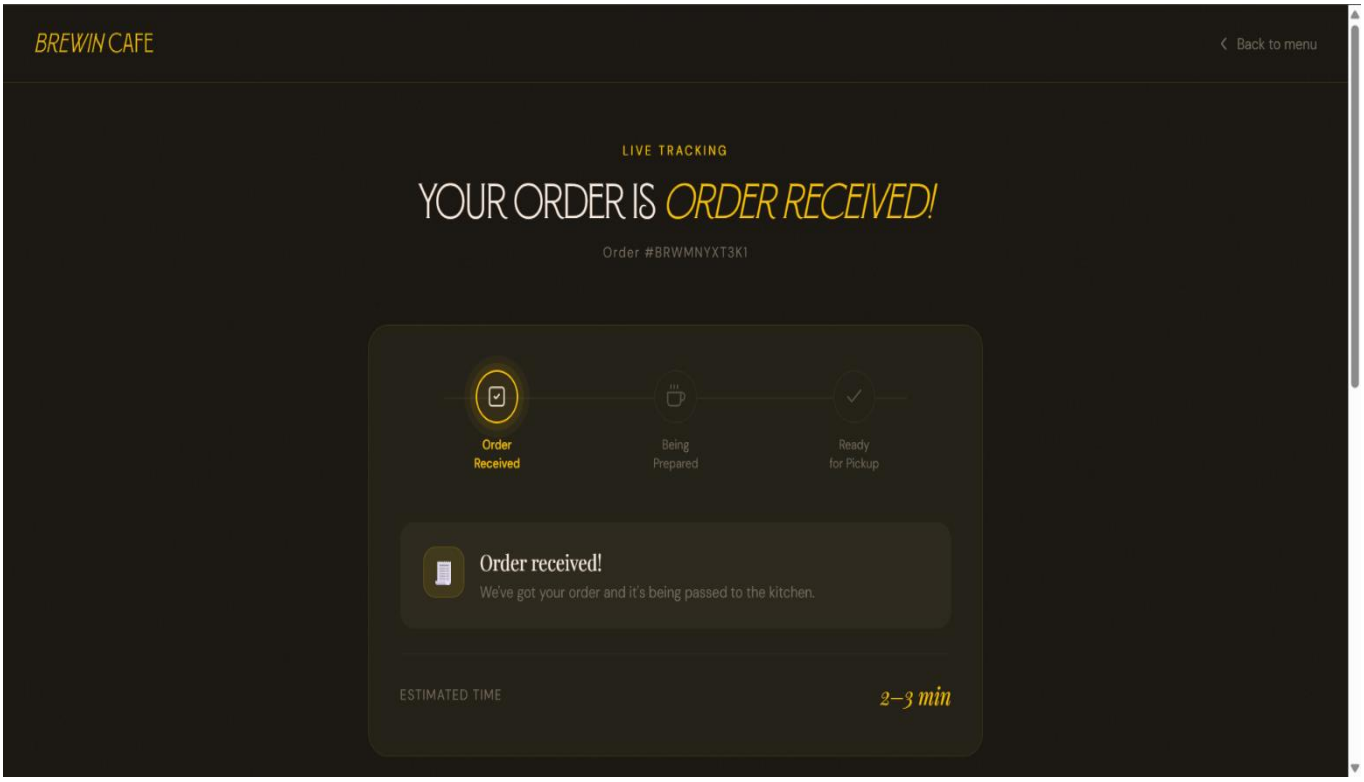
5.1.4 Live Order Tracking

The ****Live Order Tracking**** module provides customers with peace of mind by showing the real-time status of their preparation.

Dynamic Progress Timeline: The heart of this module is a visual timeline that fills up as the order moves through four distinct stages: **Confirmed**, **Preparing**, **Ready for Pickup**, and **Delivered**.

Direct Real-time Updates: The page listens for status-change events emitted by the server. When the kitchen staff updates an order's status on the KDS (Kitchen Display System), the tracking page timeline updates instantly across all connected customer devices. This eliminates the need for manual refreshes and creates a sense of transparency and speed.

D) Live Order Tracking :



5.2 Owner Management Module (KDS)

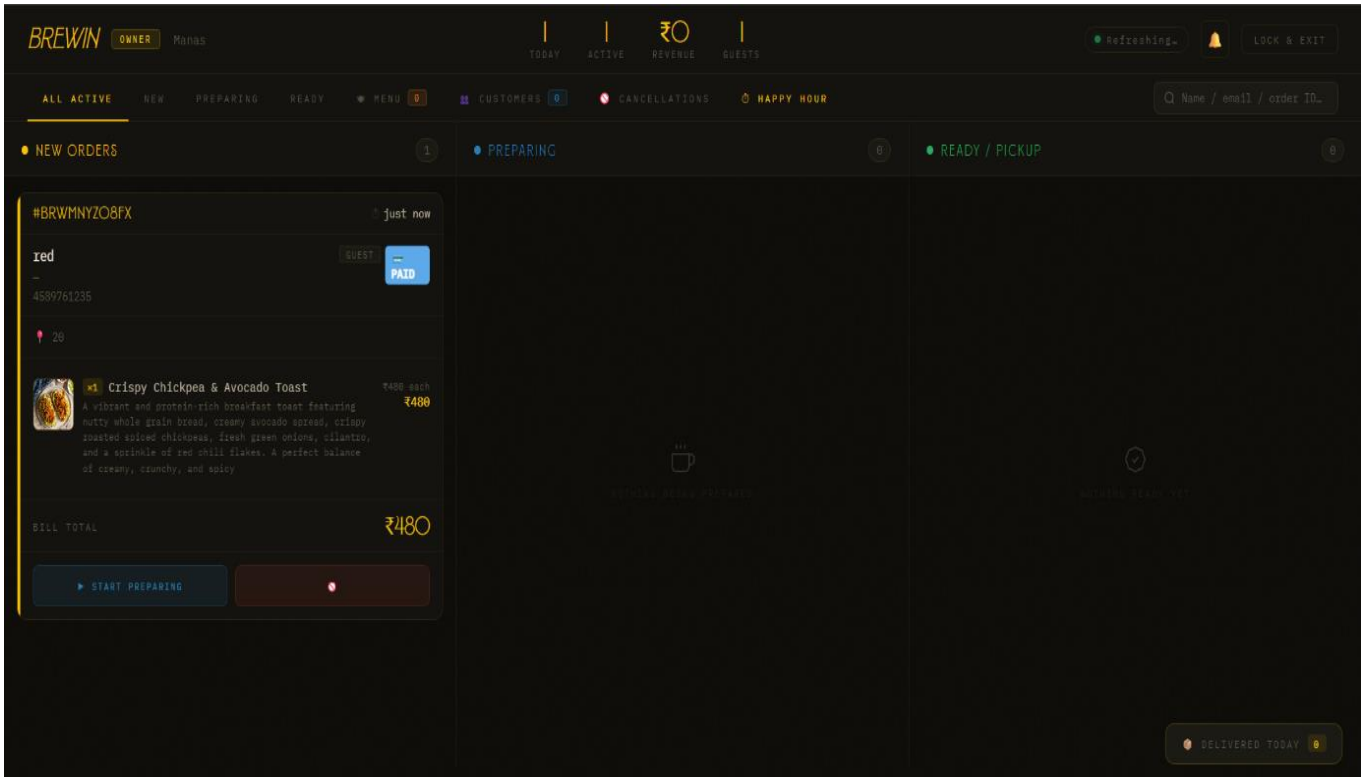
The **Kitchen Display System (KDS)** is the operational interface for the café owner and staff, designed for high efficiency in a fast-paced environment.

Real-time Order Feed: New orders appear as organized cards instantly upon payment verification. Each card contains the human-readable Order ID, customer details, and a clear list of items to be prepared.

Kitchen Alerts : To ensure no order is missed, the module includes an audio notification system. A distinctive chime plays whenever a new "Paid" order enters the queue via the WebSocket connection.

Inventory Management: The owner has a dedicated interface to manage product availability. With a single toggle, any item can be marked as available or unavailable. This change is immediately broadcasted to all active customer browsers, ensuring the digital menu is always in sync with the physical kitchen stock.

E) Owner Management Module (KDS) :



CHAPTER 6: SOFTWARE TESTING

The software testing phase is a critical component of the development lifecycle, ensuring that the **Brewin Café** system is not only functional but also resilient, secure, and user-friendly. In a modern web application that relies on real-time state synchronization and financial transactions, testing serves as the ultimate safeguard against data loss and poor user experience. This chapter details the comprehensive testing strategies employed to validate every layer of the application.

6.1 Testing Methodologies

The project adopted a layered testing methodology, moving from localized code validation to broad system-wide checks. This approach ensures that bugs are caught at the earliest possible stage, reducing the complexity of debugging in the later phases of the project.

6.1.1 Unit Testing & API Verification

Unit testing focuses on the smallest individual units of the backend logic. In the context of Brewin Café, this meant isolating the core functions responsible for data transformation and business rules. Each API endpoint was subjected to rigorous verification using **Postman**. The testing process was designed to ensure that the server consistently adhered to its defined contract, providing predictable responses even when faced with malformed or missing data.

For example, when testing the product management module, we verified that the server could gracefully handle requests to fetch non-existent items or update stock levels with invalid characters. This "negative testing" is essential for preventing server-side crashes and ensuring that the application can withstand unexpected user behavior or malicious inputs without compromising the stability of the entire service.

6.1.2 Integration & Data Flow Testing

Integration testing shifts the focus from individual units to the relationships between different system modules. In a MERN stack application, the most vital integrations occur between the **React** frontend, the **Express** server, and the **MongoDB** database. Our integration tests were designed to trace the movement of a single data packet from initial user input to final database persistence.

Detailed testing was performed on the order-creation pipeline. This involved verifying that a "Checkout" action in the browser correctly triggered the creation of a temporary order document, initialized a payment session with the Razorpay cloud servers, and successfully updated the final document status only upon receiving a cryptographically verified success signal. This cross-module verification ensures that the "handshake" between various service layers is seamless and error-free.

6.1.3 User Acceptance Testing (UAT) & UX Polish

User Acceptance Testing is the final layer of validation, centered entirely on the human element of the application. Since Brewin Café utilizes **GSAP** for high-end micro-interactions, it was imperative to test these animations on various hardware profiles. UAT involved "story-driven" testing, where testers followed specific user personas—such as a first-time visitor or a returning café owner—to identify any friction points in the interface.

We focused heavily on the visual feedback loops. For instance, when a user adds an item to the cart, the system must provide immediate, high-quality visual confirmation. Similarly, when the kitchen updates an order status, the customer's tracking page must update without the jitter or lag that can occur in poorly optimized real-time systems. This phase ensures that the technical implementation meets the high aesthetic standards set during the project's conceptual design.

6.2 Testing Environment & Quality Assurance

To ensure the application reaches a production-ready standard, it was validated across an exhaustive range of simulated environments and physical hardware. This process ensures that the premium experience remains consistent regardless of the user's choice of technology.

6.2.1 Cross-Browser Rendering & Logic Verification

The application was subjected to rigorous testing on Google Chrome, Apple's Safari, and Mozilla Firefox. This was a non-negotiable step because rendering engines—such as Blink and WebKit—often interpret CSS properties like backdrop blurs and staggered animations with slight variations. By verifying the logic on all three platforms, we ensured that the GSAP timelines remained synchronized and that the visual "glassmorphism" effects didn't cause performance degradation or layout shifts in older browser versions.

6.2.2 Mobile Responsiveness & Adaptive Layouts

Using both physical mobile devices and the Chrome Device Emulator, we tested the application across dozens of screen resolutions. This included edge cases such as ultra-narrow vertical screens (iPhone SE) and large horizontal tablets (iPad Pro). The goal was to ensure that the product grid scaled proportionately and that interactive elements like the "Cart Drawer" were easily accessible via touch gestures. We paid specific attention to the "Safe Areas" on modern smartphones to ensure that the bottom navigation bar didn't overlap with system indicators.

6.2.3 Network Stability & Real-time Recovery

In a real-world scenario, customers often order while moving, leading to intermittent network connectivity. We simulated these conditions using network throttling (Slow 3G) and sudden connection drops. The system was tested to ensure that the **Socket.io** client could automatically reconnect and fetch the latest order status without requiring a manual refresh. We also verified that the application's local state management could persist the user's cart even if their internet connection was completely lost during the browsing phase.

6.2.4 Boundary Value & Security Robustness

Security was a paramount concern throughout the testing phase. We performed manual penetration tests to ensure that the system's role-based access control (RBAC) was impenetrable. This included attempting to bypass the owner dashboard's authentication layer by manually manipulating the browser's URL. Additionally, we tested boundary values for financial inputs—ensuring that the system could never process an order with a zero or negative total—thereby protecting the café owner from potential edge-case exploits.

CHAPTER 7: CONCLUSION & BIBLIOGRAPHY

7.1 Conclusion

The primary objective of the **Brewin Café** project was to develop a high-performance, real-time ordering system that eliminates the manual inefficiencies of traditional coffee shop operations. By successfully implementing a full-stack solution using the **MERN** suite, the project has demonstrated that modern web technologies can create an experience that is both functionally robust and aesthetically premium. The integration of **Socket.io** proved to be the cornerstone of the application, bridging the gap between the customer's front-end tracker and the owner's back-end dashboard with zero latency.

Throughout the development lifecycle, several critical milestones were achieved. The most significant was the successful implementation of a completely automated, secure checkout process via **Razorpay**, providing customers with the convenience of digital payments while ensuring the business owner receives instant verification. Furthermore, the use of **GSAP** for entrance animations and state transitions has elevated the user interface from a simple website to a high-end digital brand experience. In summary, **Brewin Café** stands as a testament to the power of real-time web applications to transform physical hospitality into a streamlined, digital-first operation.

7.2 Future Scope

While the current version of **Brewin Café** offers a comprehensive feature set for any modern café, the architecture has been designed with future scalability in mind. There are several promising avenues for growth that could further enhance the customer experience and operational efficiency.

One immediate area for enhancement is the integration of **AI-Powered Personalized Recommendations**. By analyzing a customer's previous order history and time of visit, the system could suggest pairings—such as recommending a warm croissant when a user selects a Latte during morning hours. This data-driven approach

not only improves user convenience but significantly increases the average order value for the business.

Another strategic step forward involves the development of **Native Mobile Applications** using frameworks like React Native. While the current web interface is fully responsive, native apps would allow for the implementation of push notifications. These notifications would inform customers of "Happy Hour" deals in real-time or provide lock-screen updates on their order status, creating a deeper level of engagement with the brand.

Finally, the system could be expanded into a **Multi-Branch Management Platform**. The current dashboard is optimized for a single location, but the database architecture is flexible enough to support multiple outlets under a single owner profile. This would allow a proprietor to monitor sales, inventory, and order performance across multiple branches from a single unified interface, making Brewin Café a truly enterprise-grade solution for growing hospitality brands.

7.3 Final Reflections

Developing this project has provided invaluable insights into the complexities of building real-time, event-driven applications. Balancing high-end visual animations with the strict performance requirements of a kitchen display system required a deep dive into state management and WebSocket optimization. The journey from conceptualizing the first "loader" animation to verifying the final payment signature on the server has been a rigourous exercise in full-stack engineering, reinforcing the importance of clean architecture and user-centric design in the modern digital landscape.

BIBLIOGRAPHY 📚

The development of **Brewin Café** was supported by a wide range of academic resources, technical documentation, and community-driven knowledge bases. The following references were instrumental in the project's realization:

1. **MDN Web Docs (Mozilla Developer Network)**: Utilized extensively for cross-browser CSS Grid patterns, Flexbox layouts, and ES6+ JavaScript syntax standards.

2. **Node.js & Express Documentation**: Served as the primary reference for architecting the RESTful API and implementing secure middleware for JWT-based authentication.

3. **Socket.io Official Documentation (v4.x)**: Provided the architectural patterns for low-latency WebSocket communication and event-room management.

4. **Razorpay Developer Hub**: Used for integrating the payment gateway SDK, handling webhook events, and implementing cryptographic signature verification for secure transactions.

5. **MongoDB University (M220P)**: Information regarding document-oriented database modeling, specifically the implementation of embedded arrays for order items.

6. **GSAP (GreenSock Animation Platform) Documentation**: The definitive source for implementing high-performance, staggered entrance animations and ScrollTrigger effects.

7. **Postman Learning Center**: Reference for designing and automating the API testing suite used during the development lifecycle.
